This invention relates to a testing device to test various types of semiconductor devices. In the semiconductor industry, semiconductor devices such as transistors are mass-produced by arranging a large number of units of a test circuit formed on a semiconductor substrate such as a silicon semiconductor substrate or a gallium arsenide semiconductor substrate or a silicon-on-insulator (SOI) substrate on a test tray, testing the function of each unit by means of a tester and recording the result of the testing. This is called "wafer level test". The test tray includes a table and a support plate for supporting the semiconductor substrate in a predetermined position. The support plate is a so-called paddle. The paddle is attached to the table at a lower portion thereof, and can be displaced upwardly. According to this testing system, the table and the paddle can move relatively to each other. By
