If so, how?
A: You can pass the path in the ViewBag as shown: ViewBag.Url = ""; Then in the View: Link And on the Controller side, you could set the Route Values with the URL. Q: Angular: Binding inside an ngIf I have the following html. {{task.name}} But the issue I am having is trying to bind {{task.name}} into the div. What I want is not for {{task.name}} to be visible on the screen. If this is something which would be easy to fix, or my approach is wrong please let me know! Also, if there is a way to do this without an *ngFor, I would be interested in knowing! A: I see a few things in your code. This is not valid HTML You will want to use *ngIf for this Use of *ngFor is not recommended. If you are going to go this route, make sure that

@CR11)^. This data is represented using the Circos graphic (Fig. [1c](#Fig1){ref-type="fig"}) in which protein-interaction data is over-plotted to show co-expression of the proteins as grey concentric rings and the interaction data as black lines[@CR12]^ . Comparisons of expression and interaction data reveal many interactions between proteins that are not co-expressed in breast cancer. For example, insulin-like growth factor 2 receptor (IGF2R) is known to be overexpressed in breast cancer[@CR13]^; however, there are no known interactions between IGF2R and any of the other proteins in the network. It is also interesting to see that the majority of interacting proteins are nuclear, rather than cytoplasmic. It has previously been demonstrated that the cytoplasmic proteome in breast cancer is severely depleted of protein-protein interactions[@CR14]^ and it is possible that nuclear proteins have a more significant role in cancer biology than previously expected. Up to date, large-scale studies in breast cancer have been performed using technologies such as microarrays to identify mRNA changes. A subset of these mRNA changes have been verified at the protein level using mass spectrometry. However, this method does not allow comprehensive analysis and validation of the whole proteome. Biologically, we would expect a protein to be regulated at both the mRNA and protein level; however, it is also possible for a protein to be regulated only at the protein level. The interplay between gene/protein expression levels and the biophysical interactions of proteins must be tightly regulated and controlled in cells to ensure correct functioning of the cell. Disruption of these interactions could lead to aberrant cell cycle progression, growth and survival. The interactions between proteins are mediated by a number of factors, including post-translational modifications of proteins such as phosphorylation, ubiquitination and acetylation[@CR15]-[@CR17]^ . Many of these modifications, in particular phosphorylation, occur in a reversible way which could be important to ensure that the interaction proteins remain functional. Currently, the techniques available to study protein-protein interactions include co-immunoprecipitation, co-localisation, yeast-two-hybrid, bimolecular fluorescence complementation (BiFC), biomolecular complementation and photo-cross
