Discrete mechanics In discrete mechanics, discrete forms of mechanical motion are considered for the purpose of studying systems with a discrete set of points. The finite elements method is an example, while solutions in terms of fast Fourier transforms are used to simulate objects composed of a large number of points. Velocity interpolation, a way of computing

discrete velocity, is required for the simulation of fluid flow. Discrete mechanics is commonly treated in the context of computer graphics and computer games. In the field of programming languages the term dynamic mode discrete computing is used for the study of discrete mechanics. It is an abstract model of computation. Discrete mechanics for animation Discrete mechanics are primarily used to simulate particle systems, such as balls and bullets, computer-generated objects, such as a bridge, a tree, or a skyscraper, or even ballistics, dynamics and aerodynamics. Sometimes, the objects are not simulated by simulation, but by “directing the path” of the particles (also called “actors”). One of the most common techniques is to represent a complex system of points and their interactions by developing a tree or hierarchy of paths. Each node in the tree

represents one part of the system, such as a sphere or the walls of a room. When a simulation needs to include hundreds or even thousands of objects, a programmer would direct the motion of each object according to the path defined in the tree. A basic requirement for a tree structure is the ability to compute discrete velocities. In addition, the physics of the system should be easily programmed as well. Discrete Mechanics and physics engine

While discrete dynamics are concerned with motion of discrete systems (e.g., a piece of furniture), physics engines are concerned with the physics of continuous fields. A
